When you put together two lists (even if you append a singleton list to a list, for instance: [1,2,3] ++ [4]), internally, Haskell has to walk through the whole list on the left side of ++. That's not a problem when dealing with lists that aren't too big.

### Starting Out - Learn You a Haskell for Great Good!

Thanks to Haskell's laziness, even if you map something over a list several times and filter it several times, it will only pass over the list once. Let's find the largest number under 100,000 that's divisible by 3829. To do that, we'll just filter a set of possibilities in which we know the solution lies.

### Higher Order Functions - Learn You a Haskell for Great Good!

A Fistful of Monads. When we first talked about functors, we saw that they were a useful concept for values that can be mapped over. Then, we took that concept one step further by introducing applicative functors, which allow us to view values of certain data types as values with contexts and use normal functions on those values while preserving the meaning of those contexts.
